
One tile = one EAU (34,223 ha); outlines are Wetland Management Districts. Value = gross probability that unprotected suitable habitat standing at the start of the decade converts by its end. It is a rate per unit of habitat, not an amount of habitat at risk. Wet and dry GCMs share one risk surface within an RCP. Class breaks are pooled across all six panels, so colours are directly comparable across years and RCPs.
The 2020 column is the shared baseline used by every scenario (mean of the RCP 4.5 and 8.5 rates), so its two rows are identical by construction.
